# NDT PoD vs. Reliability

## In the Sustainment Environment

## What is POD?

**POD is a statistical measure of the detection of a defect that is present**

**POD - probability that a defect with specific properties will be detected, under specific inspection conditions, given that there is such a defect in the material scanned**

## **What Does POD Tell Us?**

- **Determines size of defects inspection method is capable of finding**
- **Indicates proportion of defects that are detected**
- **Compares performance of system, inspector, technique, etc.**
- **Allows comparison of two or more methods**

## How Do We Use the Info?

- **Optimize an inspection**
- **Select an inspection method(s)**
- **Determine effect of inspection on life as part of overall life management system**
- **Define schedule for in-service inspection**

But . . .

How are we actually doing in the field with regard to the likelihood of something really bad happening?

. . . This is reliability

Robert Sumwalt of the NTSB quoted safety expert Jim Schultz who says,  
“Don’t ever believe that a lack of accidents means you’re safe.”

### Variables

- **Inspector** – disciplined or complacent?
- **Equipment** – what is equivalent?
- **Environment** - wide variations, not always an opportunity to use all techniques certified for
- **Procedures** - wide variations
- **Communication** – many people involved
- **Business pressures** – cost & schedule
- **Flaw variations** – no two flaws are alike
- **Training** – Focuses on industrial NDT

### Which variables can we influence?

In order to maximize **real world performance** we need to address:

### Reliability

#### Proficiency

Hands-on, practical

#### Currency

General & Specific  
NDT Knowledge

#### Risk

#### Assessment

Stress & Failure  
Damage Tolerance  
Maintenance System  
Aircraft Operation

### Proficiency

(Hands-on, practical)

**So how do we do this?**

- **Individual performance**
  - ✓ **Hit / Miss**
  - ✓ **PoD curves**
- **A sample of POD specimens inspected by a variety of experienced technicians using their own equipment**

# NDT PoD vs. Reliability In the Sustainment Environment

## Hit / Miss Data from POD Specimens

- 420 sites
- 68 defects
- 29–71% detection rate
- 0.058" – 0.286" missed
- 3 missed were over 0.100"

### Individual POD Curves

### Currency

(General & Specific NDT Knowledge)

### Quizzes

- Unannounced quizzes were given at the beginning of several refresher seminars. Questions were taken from published general exams.
- Only one or two in each class passed, most scores were in the 40s and 50s.

## In the Sustainment Environment

So what does all this tell us?

- **This does not imply that technicians don't know what they are doing.**
- **Flaws are being missed that are significantly larger than the accepted POD values.**
- **There is considerable variation in the performance of individual technicians.**
- **Our general knowledge gets stale when years pass since our certification exams.**

# NDT PoD vs. Reliability

## In the Sustainment Environment

## Risk Assessment

- **Aircraft history** – previous inspection results
- **Aircraft mission** – pax, cargo, etc.
- **When is the next inspection** – if you miss, is it likely to be found at the next
- **Safety risk** – what if you accept it and you're wrong
